

### REMARKS

This Preliminary Amendment cancels the original claims, without prejudice, in the underlying PCT Application No. PCT/DE03/01961. The Preliminary Amendment also adds new claims 14-28. The new claims conform the claims to U.S. Patent and Trademark Office rules and do not add new matter to the application.

In accordance with 37 C.F.R. § 1.125(b), the Substitute Specification (including the Abstract) contains no new matter. The amendments reflected in the Substitute Specification (including Abstract) are to conform the Specification and Abstract to United States Patent and Trademark Office rules or to correct informalities. As required by 37 C.F.R. §§ 1.121(b)(3)(ii) and 1.125(c), a Marked-Up Version of the Substitute Specification comparing the Specification of record and the Substitute Specification also accompanies this Preliminary Amendment. Approval and entry of the Substitute Specification (including Abstract) are respectfully requested.

The underlying PCT Application No. PCT/DE03/01961 includes an International Search Report, dated June 12, 2003, a copy of which is submitted herewith.

Applicants assert that the subject matter of the present application is new, non-obvious, and useful. Prompt consideration and allowance of the application are respectfully requested.

Respectfully submitted,

KENYON & KENYON

## METHOD FOR OPERATING AN INTERNAL COMBUSTION ENGINE

~~Background Information~~FIELD OF THE INVENTION

The present invention is directed to a method for operating an internal combustion engine, in which the ambient pressure is determined by an ambient pressure sensor and the pressure in an intake manifold of the combustion engine is determined by an intake manifold pressure sensor, and in which the reliability performance of the ambient pressure sensor is checked by comparing the ambient pressure to a starting value that is obtained before or during the starting process of the combustion engine.

BACKGROUND INFORMATION

Such a method is ~~known from DE~~ described in German Published Patent Application No. 100 21 639 C1.639. However, an additional signal ~~is necessary~~ may be required there, namely a modeled intake manifold pressure, in order to perform the check of the ambient pressure sensor.

~~Object, Achievement of the Object, and Advantages of the Invention~~

SUMMARY OF THE INVENTION

The ~~object of the present invention is to create a~~ provides an example method for operating an internal combustion engine, with which an easy and yet reliable check of the ambient pressure sensor ~~is possible~~ may be provided.

~~This object is achieved according~~ According to an example embodiment of the present invention, in ~~an example~~ method of the type named at the beginning, by performing the comparison only if a preceding check of the intake manifold pressure sensor yields the result that it is operational.

EV323019493

According to an example embodiment of the present invention, it ~~is~~may be ensured that the check of the ambient pressure sensor is only performed if the intake manifold pressure sensor has been recognized as operational. If that is not the case, checking the ambient pressure sensor ~~is~~may not be possible. Thus, according to an example embodiment of the present invention this check is made dependent on one or more release conditions that must be fulfilled. This ~~ensures~~may ensure that the check of the ambient pressure sensor ~~really~~consistently yields a correct result. Furthermore, because of the prior release conditions the entire example method ~~remains~~may remain simple and manageable.

Further features, possible applications, and advantages of the present invention derive from the following description of exemplary embodiments of the present invention, which are illustrated in the figures ~~of the drawing~~. All of the features described or illustrated represent the object of the present invention *per se* or in any combination, regardless of their summary in the patent claims or their ~~back-references~~references and regardless of their wording in the description or illustration in the drawing.

## ~~Exemplary Embodiments of the Present Invention~~

### BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 shows a schematic block diagram of an exemplary embodiment of an internal combustion engine according to the present invention, ~~and~~.

Figures 2 and 3 show schematic flow charts of an exemplary embodiment of a method for operating the internal combustion engine of Figure 1.

### DETAILED DESCRIPTION

Figure 1 illustrates an internal combustion engine 10, which is intended in particular for propelling a motor vehicle. Combustion engine 10 has an intake manifold 11 and an exhaust pipe 12. A throttle valve 13 is installed in intake manifold 11. Ambient air is supplied to combustion engine 10 through intake manifold 11. The quantity of air supplied may be influenced through throttle valve 13.

Positioned in intake manifold 11 downstream from throttle valve 13 in the intake direction is an intake manifold pressure sensor 14, which is provided for measuring the pressure in intake

manifold 11. Outside of intake manifold 11 there is an ambient pressure sensor 15 for measuring the ambient pressure.

Intake manifold pressure sensor 14 produces a signal DSS, and ambient pressure sensor 15 produces a signal DSU. Both signals DSS, DSU are fed to an electronic control unit 16 which, depending in part on signals DSS, DSU, controls and/or regulates the operating variables of internal combustion engine 10.

To diagnose the reliability performance of ambient pressure sensor 15, the following example method is performed by control unit 16. The example method is stored as a computer program on an electric storage medium, for example a flash memory, and is performed by a computer of control unit 16 by executing the individual program commands.

In this example method, release conditions are first checked, after which, if the release conditions are fulfilled, the check of ambient pressure sensor 15 is performed. The check of the release conditions is explained below on the basis of Figures 2 and 3. ~~3, 4 and 5~~ The check of ambient pressure sensor 15 takes place at the end in Figure 3.

In Figure 2 there is a bit C\_ini, which has a positive slope when the ignition of combustion engine 10 is first switched on. The positive slope results ~~very~~ generally in control unit 16 being initialized. Specifically, the positive slope of bit C\_ini results in a flip-flop 21 and a flip-flop 22 of Figure 2 being reset.

Flip-flop 21 is set if a bit B\_sta has a positive slope. This is ~~precisely~~ the case when a starting process of internal combustion engine 10 is triggered by control unit 16. This is the case if certain starting conditions are fulfilled, ~~for~~ For example, a starting process ~~has~~ may need to have been initiated by the driver, an automatic transmission ~~must~~ may be required so be in “park,” and so on.

If flip-flop 21 has been set by bit B\_sta, its output is HIGH.

Flip-flop 22 is set if the speed of internal combustion engine 10 is within a prescribed speed range. This speed range is oriented toward the actual speed that internal combustion engine 10 should have in the starting process. The speed range is defined by an upper value NDDFM and a lower value NDDFA, which are present at a comparator 23. Comparator 23 checks

whether the actual speed nist of internal combustion engine 10 is between the two values NDDFM, NDDFA, and hence within the desired speed range.

If flip-flop 22 has been set in this ~~way~~manner, a HIGH signal is present at its output, whose rising slope is relayed through a slope detector 24.

- 5 Actual angle wdk of throttle valve 13 is compared to a prescribed maximum throttle valve angle WDKBAST by a comparator 25. If actual angle WDK is smaller than this maximum throttle valve angle WDKBAST, the output of comparator 25 is HIGH.

Actual duration tnst of the starting process is compared to a prescribed maximum duration SY\_TSIDSS by a comparator 26. If duration tnst is shorter than this maximum duration

- 10 SY\_TSIDSS, the output of comparator 26 is HIGH.

The outputs of flip-flop 21, slope detector 24, and the two comparators 25, 26 are sent to an AND gate 27. If all four inputs of AND gate 27 are HIGH, its output is also HIGH.

- This is ~~exactly~~ the case when i) the ignition of internal combustion engine 10 is just turned on, ii) a starting process is triggered by control unit 16, iii) the actual speed of internal  
15 combustion engine 10 is within a desired speed range, iv) throttle valve 13 is open no wider than the maximum throttle valve angle, and v) the starting process has not yet exceeded the prescribed duration.

- This is a first part of the aforementioned release conditions that ~~must~~may be required to be fulfilled for the check of ambient pressure sensor 15 to be performed. If the conditions are  
20 fulfilled and the output of AND gate 27 is HIGH, this is recognized by function 28 and is further processed as part of the measures identified with /1/, /2/, and /3/ in Figure 2.

In measure /1/ a bit B\_psidss, which indicates whether the check of ambient pressure sensor 15 may take place, is set to "true = one." This is ~~precisely~~ the case when all release conditions are fulfilled and the output of AND gate 27 is HIGH.

- 25 Measures /2/ and /3/ relate to intake manifold pressure sensor 14. Its signal DSS is used by control unit 16 to produce a pressure psh in intake manifold 11.

Before a starting process of ~~engine internal~~internal combustion engine 10, i.e., when internal combustion engine 10 is off, pressure psh in intake manifold 11 and in particular also

the pressure downstream from throttle valve 13 is approximately the same as the ambient pressure because internal combustion engine 10 is at rest. This is equivalent to pressure psh measured by intake manifold pressure sensor 14 before a starting process being approximately the same as the ambient pressure. This pressure psh measured by intake manifold pressure sensor 14 before the starting process may thus be used to diagnose ambient pressure sensor 15.

To this end, pressure psh measured by intake manifold pressure sensor 14 before the starting process is stored by control unit 16 as starting value psh\_sta. The storage process may be carried out until the starting process, in particular until power is supplied to the starter.

According to Figure 2, current pressure psh in intake manifold 11 is subtracted from stored starting value psh\_sta by a block 29. The difference is then compared to a prescribed minimum value DPDDF by a comparator 30. If the difference is smaller than minimum value DPDDF, the output of comparator 30 is HIGH.

In this check it ~~is~~may be assumed that the pressure in intake manifold 11 drops sharply after the beginning of the starting process. Thus the difference between current pressure psh and stored starting value psh\_sta must be large. If this is the case, i.e., if minimum value DPDDF is exceeded, it may be concluded therefrom that intake manifold pressure sensor 14 is operational.

The HIGH signal at the output of comparator 30 results in bits B\_sidss and B\_drssidss being set to "true = one." This is equivalent to a defect in intake manifold pressure sensor 14. If the output of comparator 30 is LOW, the forenamed bits are set to "false = zero," which signals the reliability performance of intake manifold pressure sensor 14.

Bit B\_sidss is intended to be further processed by control unit 16. Among other things, bits B\_elm and E\_ds, explained below, are based on this bit B\_sidss. Bit B\_drssidss is stored, and may be used for example in conjunction with an inspection or repair of internal combustion engine 10 to direct the testing personnel to the defective intake manifold pressure sensor 14.

Let it be pointed out again that measures /1/, /2/, and /3/ are carried out only if the described release conditions are fulfilled and the output of AND gate 27 is HIGH.

In Figure 3 there is a flip-flop 31, which processes bits B\_sta and C\_ini in the same manner as explained earlier in connection with flip-flop 21 of Figure 2. Thus the output of flip-flop 31 is HIGH if the ignition has just been turned on and if a starting process has been triggered.

A slope detector 32 is fed a bit Z\_ds that indicates whether a diagnosis of intake manifold pressure sensor 14 has been performed. If so, the output of slope detector 32 goes HIGH. The diagnosis of intake manifold pressure sensor 14 may involve not only checking current pressure psh and stored starting value psh\_sta, as explained in connection with measures /2/ and /3/ of Figure 2. Instead, it may involve any alternative or supplemental test with which the reliability performance of intake manifold pressure sensor 14 may be checked.

Bit B\_psidss indicated in Figure 3 corresponds to the same bit that was explained in connection with measure /1/ of Figure 2.

Also present in Figure 3 is an OR element 33, to which aforementioned bits B\_elm and E\_ds are fed. If there is a HIGH signal at one of the two inputs of the OR element, this ~~means~~indicates that there is an error in connection with intake manifold pressure sensor 14.

The output of OR element 33 is thus also HIGH. The result of subsequent inverter 34 is that its output is LOW.

In the opposite case, i.e., if intake manifold pressure sensor 14 is operational, the inputs of OR element 33 are LOW, so that its output is likewise LOW. The output of inverter 34 is thus HIGH.

The outputs of flip-flop 31, slope detector 32, inverter 34, and bit B\_psidss are sent to an AND gate 35. If all four inputs of AND gate 35 are HIGH, its output is also HIGH.

This is ~~exactly~~ the case when i) the ignition of internal combustion engine 10 is turned on again, ii) a starting process is triggered by control unit 16, iii) a check of intake manifold pressure sensor 14 has been performed, iv) the release conditions explained in connection with Figure 2 have been fulfilled successfully, and v) intake manifold pressure sensor 14 is operational.

This is a second part of the aforementioned release conditions that ~~must~~may be required to be fulfilled for the check of ambient pressure sensor 15 to be performed. If the conditions are

fulfilled and the output of AND gate 35 is HIGH, this is detected by function 36 and is further processed as part of the measures identified with /1/, /2/, and /3/ in Figure 3.

In measure /1/ a bit B\_pplds, which indicates that the check of ambient pressure sensor 15 may take place, is set to "true = one." This is precisely the case when all release conditions of Figure 2 and all the above release conditions of Figure 3 are fulfilled and the output of AND gate 35 is HIGH.

Measures /2/ and /3/ relate to the check of ambient pressure sensor 15. This check is explained below.

Control unit 16 uses signal DSU from ambient pressure sensor 15 to produce an ambient pressure pu. Also present in control unit 16 is a signal puroh, which represents the ambient pressure that has not been filtered or checked for plausibility. In addition, control unit 16 performs tests with which it determines whether signal DSU of ambient pressure sensor 15 is at all reasonable or plausible. The result of this test is present as bit E\_ds.

Ambient pressure pu and signal puroh are fed to a selector switch 37, which is controlled by bit E\_ds. If bit E\_ds indicates that ambient pressure sensor 15 is delivering a plausible signal DSU, then ambient pressure pu obtained from ambient pressure sensor 15 is relayed by selector switch 37. If not, signal puroh is relayed.

We shall assume now that the first case exists, and that ambient pressure pu obtained from ambient pressure sensor 15 is therefore present at the output of selector switch 37.

Stored starting value psh\_sta is subtracted from ambient pressure pu by a block 38, according to Figure 3. The absolute value is determined from the difference by a block 39. This result is compared to a maximum value DPMAX by a comparator 40. If the absolute value of the difference between ambient pressure pu and stored starting value psh\_sta is greater than maximum value DPMAX, then the output of comparator 40 is HIGH.

Underlying the above procedure is the consideration, mentioned earlier, that starting value psh\_sta measured by intake manifold pressure sensor 14 before the starting process and then stored is approximately the same as the ambient pressure. Thus if it is determined on the basis of the release conditions that intake manifold pressure sensor 14 is not defective, and that a correct starting process has taken place, then after this starting process ambient pressure pu

obtained from ambient pressure sensor 15 must be approximately the same as stored starting value psh\_sta.

At the same time, however, this ~~means~~indicates that the absolute value of the difference between ambient pressure pu and starting value psh\_sta may only be very small. This is

5 checked through the comparison with maximum value DPMAX. If maximum value DPMAX is not exceeded, it is concluded that ambient pressure sensor 15 is not defective; ~~this~~. This is indicated by a LOW signal at the output of comparator 40. But if maximum value DPMAX is exceeded, a defect of ambient pressure sensor 15 is concluded, and the output of comparator 40 is HIGH.

10 In the case of a supercharged internal combustion engine 10, a starting value pll\_sta is also subtracted from ambient pressure pu by a block 41, according to Figure 3. Starting value pll\_sta is comparable to starting value psh\_sta. Both starting values are measured prior to the starting process and then stored. Because the two starting values are measured prior to the starting process, it is assumed that they are approximately the same as the ambient pressure.

15 As explained earlier, starting value psh\_sta is measured by intake manifold pressure sensor 14, whereas starting value pll\_sta is measured by a charge air pressure sensor, which is located inside the device that is used to charge internal combustion engine 10.

The absolute value is determined by a block 42 from the difference between ambient pressure pu and stored starting value pll\_sta. This result is then compared by a comparator 43 to  
20 maximum value DPMAX mentioned earlier. If the absolute value of the difference between ambient pressure pu and starting value pll\_sta does not exceed maximum value DPMAX, it is concluded that ambient pressure sensor 15 is operational, and the output of comparator 43 is LOW.

The outputs of comparator 40 and comparator 43 act on an AND gate 44. If both of these  
25 outputs are HIGH, then the output of AND gate 44 is also HIGH.

It should be pointed out that the described check based on stored starting value pll\_sta, i.e., based on the charge air pressure of a supercharged internal combustion engine 10, represents a possibility which may also be dispensed with. In that case, blocks 41, 42, 43, and 44 are not present. It is also possible, in all of the functions and measures that were explained earlier or  
30 still remain to be explained in connection with intake manifold pressure sensor 14, for this intake manifold pressure sensor 14 to be replaced by the forenamed charge air pressure

sensor. In that case, the charge air pressure sensor represents an alternative to intake manifold pressure sensor 14 in regard to the check of the ambient pressure sensor.

A HIGH signal at the output of AND gate 44 results in bits B\_pldsu and B\_drpldsu being set to "true = one." This is equivalent to a defect in ambient pressure sensor 15. If the output of  
5 AND gate 44 is LOW, the forenamed bits are set to "false = zero," which signals the reliability performance of ambient pressure sensor 15.

Bit B\_pldsu is intended to be further processed by control unit 16. Bit B\_drpldsu is stored, and may be used for example in conjunction with an inspection or repair of internal combustion engine 10 to direct the testing personnel to defective ambient pressure sensor 15.

10 Let it be pointed out again that measures /1/, /2/, and /3/ of Figure 3 are carried out only if the described release conditions of Figures 2 and 3 are fulfilled and the output of AND gate 35 is HIGH.

If ambient pressure sensor 15 has been detected as defective, it is possible to replace ambient pressure pu, itself obtained from ambient pressure sensor 15, in another waymanner. If intake  
15 manifold pressure sensor 14 has been recognized as operational, this may be accomplished by continuing to use starting value psh\_sta, i.e., the pressure in intake manifold 11 prior to the starting process, as a constant ambient pressure. This replacement of ambient pressure pu by starting value psh\_sta may then be repeated after each starting process. If ambient pressure sensor 15 should be recognized as operational again, the above replacement may be canceled.

20 The described method ±maybe suitable not only for checking ambient pressure sensor 15, but in general for checking any pressure sensor that comes into contact with the environment of internal combustion engine 10, at least before the latter is started. For example, a charge air pressure sensor or an air filter pressure sensor ±maybe suitable for sensing an ambient pressure before internal combustion engine 10 is started. This ambient pressure may then be  
25 compared (block 38) to starting value psh\_sta determined by intake manifold pressure sensor 14, in accordance with the above description. That may be used to reach a conclusion about the reliability performance of the charge air pressure sensor or the air filter pressure sensor (block 40).

~~Abstract~~

ABSTRACT OF THE DISCLOSURE

A method for operating an internal combustion engine (10) is described, in which the ambient pressure is determined by an ambient pressure sensor (15) and the pressure in an intake manifold (11) of the internal combustion engine (10) is determined by an intake manifold pressure sensor (14). In this method the reliability performance of the ambient pressure sensor (15) is checked by comparing the ambient pressure to a starting value that is obtained by the intake manifold pressure sensor (14) before a starting process of the internal combustion engine (10). The comparison is only performed if a preceding check of the intake manifold pressure sensor (14) yields the result that it is operational.
